SYNTHESIS OF ENANTIOPURE 8-AMINOMETHYLINDOLIZINES FROM GLUTAMINE BY STEREOELECTRONICALLY CONTROLLED CATIONIC CYCLIZATION

Thomas Lehmann and Peter Gmeiner*

Department of Medicinal Chemistry, Emil Fischer Center, Friedrich-Alexander University, Schuhstraße 19, D-91052 Erlangen, Germany

Abstract - Starting from natural glutamine the synthesis of the 8-aminomethylindolizine (4b) was accomplished. The construction of the ring system was performed by employing a cationic 6-exo π-cyclization of an intermediate aziridinium salt. Transformation of the N,N-dibenzyl protected amine (4b) into the pharmacologically relevant target compound (11) is also described.

The exploitation of cationic π-cyclizations in the construction of a variety of ring systems has been the object of intense studies in the field of heterocyclic chemistry.1 Employing N-pyrrole-terminated cyclization precursors this strategy gives access to tetrahydroindolizines and tetrahydropyrrolo[1,2-a]azepines.2,3 As a part of our ongoing efforts to design selective dopamine D2/D3 autoreceptor agonists4 which are of potential interest for the treatment of schizophrenia and cocaine craving,5 we used cationic π-cyclizations for the construction of enantiomerically pure 6- and 7-dipropylaminotetrahydroindolizines revealing highly interesting receptor binding profiles.6 The ex-chiral pool synthesis of the 7-amino regioisomers was performed by chemoselective functionalization of asparagine (Asn), incorporation of a pyrrole moiety by Paal-Knorr reaction to furnish 1a and O-activation of the side chain.7 Since we were aware that sulfonylation of N,N-dibenzyl protected 1,2-amino alcohols and subsequent intermolecular nucleophilic substitution can result in rearrangements through aziridinium intermediates,8 we elucidated the structure of the product very carefully. In fact, a 6-endo process leading to the indolizine (3a) was observed exclusively. 5-Exo attack of 2a to give the pyrrolizine derivative (4a) could not be detected. As an extension of our studies, we intended to investigate the synthesis of the homologous 1,2-amino alcohol (1b) which should be available from natural glutamine (Gln). After O-activation the cyclization behavior of the resulting aziridinium derivative (2b) should be examined. Besides the application of the synthesis for extending our structure activity relationship
studies, we were intrigued by the question whether the 7-endo process leading to the pyrroloazepine (3b) or the 6-exo reaction giving the aminomethylindolizine (4b) would be favored.

In practice, natural glutamine (Glu) was transformed into the N,N-dibenzyl protected ester (5) according to our recently reported protocol. Subsequent borane reduction gave the diamino alcohol (6) in 84% yield which could be readily transformed into the cyclization precursor (1b) by Paal-Knorr reaction when 2,5-dimethoxytetrahydrofuran was employed as a valuable succinaldehyde equivalent.

Cyclization could be induced by activation of the 1,2-amino alcohol (1b) with trifluoromethanesulfonic anhydride when the 6-exo reaction pathway was observed, exclusively. Besides the main product (4b), we isolated a small amount of a side product which gave very similar 'H NMR and 'C NMR spectra. However, instead of the diagnostic signal for the proton in position 3 trifluoromethanesulfonyl substitution was observed indicating electrophilic attack of Tf₂O to give the side product (7). Although, the diagnostic chemical shifts and coupling patterns of the heterocycles (4b) and (7) showed high agreement with those of the tetrahydroindolizines we had prepared earlier, the tetrahydropyrrolo[1,2-a]azepine structure could not be excluded unambiguously on this stage of the synthesis. However, the following reactions, which were performed in order to exchange the N,N-dibenzyl protection by the pharmacophoric N,N-dipropyl substitution and to investigate the enantiomeric integrity of the synthesis, confirmed our assumption. In detail, hydrogenolysis using Pd(OH)_2 as a catalyst afforded a mixture of the primary amine (8a) (25%) and the
secondary amine (8b) (41 %) besides 20 % of the starting material when the hydrogenation was terminated after 45 min. When the reaction was run overnight the yield of the target compound (8a) could be increased to 59 %. Under these conditions, the octahydroindolizine (9) was formed as an easily separable side product. Careful analysis of diagnostic coupling constants in the $^1$H NMR spectrum followed by H,H-COSY and C,H-COSY as well as NOE experiments clearly proved both the aminomethylindolizine structure and the configuration at the newly generated stereogenic center in position 8a. Especially, the coupling pattern for the exocyclic methylene group (2.58 ppm, dd, $J = 12.7, 9.3$ Hz and 2.91 ppm, dd, $J = 12.7, 4.0$ Hz) clearly indicated the N-CH$_2$-CH substructure. Significant dipolar exchange of magnetism was observed between the axially orientated proton in position 8a and the exocyclic methylene group which showed also a strong NOE with respect to the axial proton in position 7. This reveals that these structural units are located at the same side of the ring indicating (8aR)-configuration.
A further interesting side reaction was observed when we transformed the primary amine (8a) into the pharmacological test compound (11) by reductive alkylation. Besides the expected N,N-dipropyl derivative equal amounts of the pyrrolonaphthyridine (12) were isolated. Obviously, an iminium typed intermediate gave an intramolecular electrophilic attack resulting in 6-endo trig ring closure. Careful structural analysis including H,H-COSY, C,H-COSY and NOE experiments (significant 1,3-diaxial interaction between the axially positioned C1 and C3 protons was observed) clearly proved chair conformations for the 6-membered rings and (S)-configuration in position 3.

Finally, examination of the enantiomeric integrity of the synthesis was performed by derivatization of the primary amine (8a) with (S)- and (R)-1-phenylethyl isocyanate. NMR analysis of the crude ureas (10a) and (10b) clearly indicated isomeric purity, when only one set of signals could be observed, respectively. Significant downfield shift for the NCH₂ protons due to N-carbamoylation confirmed the cationic 6-exo ring closure earlier in the synthesis.

**EXPERIMENTAL**

**General:** Solvents and reagents were purified and dried by standard procedures. Unless otherwise noted reactions were conducted under dry N₂. Flash chromatography was carried out with 230-400 mesh silica gel. Optical rotation was measured on a Perkin-Elmer Polarimeter 241. IR spectra were recorded on a JASCO FT/IR-410 spectrophotometer. MS and HRMS were run on Finnigan MAT TSQ 70 and 8200 spectrometers, respectively. ¹H NMR spectra were obtained on a Bruker AM 360 (360 MHz) spectrometer, if not otherwise stated in CDCl₃ relative to TMS; ¹³C-NMR spectra were run on Bruker AC 250 (63 MHz) or AM 360 (90 MHz) in CDCl₃ relative to the solvent resonance (δ = 77.0).

**(S)-2-N,N-Dibenzylamino-5-N-pyrrolylpentan-1-ol (1b)**

To a mixture of 6 (5.90 g, 19.77 mmol) and NaOAc (32.45 g, 395.12 mmol) in HOAc (300 mL) was added 2,5-dimethoxytetrahydrofuran (2.89 g, 21.87 mmol) at rt. After stirring for 75 min at 70 °C the solution was concentrated. Then, 2N NaOH and Et₂O were added. The organic layer was evaporated and MeOH (200 mL) and K₂CO₃ (100 mL, 8 % in H₂O) were added. After stirring for 24 h at rt the mixture was evaporated and the residue was extracted by Et₂O. The organic layer was dried (MgSO₄) and evaporated and the residue was purified by flash chromatography (petroleum ether - EtOAc 4:1) to give pure 1b (4.50 g, 66 %) as a colorless oil. [α]D²³ +68.5° (c = 0.9, CHCl₃); IR (NaCl) ν 3600-3200, 3025, 2930, 2860, 1495, 1455, 1280, 1090, 1030, 750, 725, 700 cm⁻¹; ¹H NMR (360 MHz) δ 1.13-1.27 (m, 1H, H-3), 1.61-1.85 (m, 3H, H-3 and H-4), 2.71-2.82 (m, 1H, H-2), 2.85-3.03 (br s, 1H, OH), 3.39 (d, J = 13.4 Hz, 2H, NCH₂Ph), 3.44 (dd, J = 10.6, 9.8 Hz, 1H, H-1), 3.49 (dd, J = 10.6, 5.8 Hz, 1H, H-1), 3.77 (d, J = 13.4 Hz, 2H, NCH₂Ph), 3.81-3.88 (m, 2H, H-5), 6.14-6.19 (m, 2H, NCHCH), 6.61-6.65 (m, 2H, NCHCH), 7.21-7.34 (m, 10H, ar); ¹³C NMR (63 MHz) δ 22.3 (H₂C-3), 29.0 (H₂C-4), 49.4 (H₂C-5), 53.3 (NCH₂Ph), 58.7 (HC-2), 60.9 (H₂C-1), 108.1 (NCHCH), 120.4 (NCHCH), 127.3 (HC-Ar), 128.5 (HC-Ar), 129.0 (HC-Ar), 139.1 (C-Ar); CI-MS (isobutane) m/z 349

1-[(1'R)-1'-Phenylethyl]-3-[(8R)-5,6,7,8-tetrahydroindolizin-8-ylmethyl]urea (10b)

Reaction of 8a with (R)-1-phenylethyl isocyanate employing conditions as described for 10a afforded 10b (33 mg, 84 %) as a colorless oil. 

\[ \text{[a]} \overline{\alpha}_{D}^{23} +37.8° \text{ (c = 1.0, CHCl}_3); \text{ IR (NaCl) } v 3335, 2930, 2865, 1630, 1565, 1255, 700 \text{ cm}^{-1}; \]

\[ \text{(R)-8-N,N-Dipropylaminomethyl-5,6,7,8-tetrahydroindolizine (11) and} \]

\[ \text{(3S,9aR)-3-Ethyl-2-N-propyl-2,3,7,8,9,9a-hexahydro-1H-pyrrolo[3,2,1-ij][1,6]naphtyridine (12)} \]

To a solution of 8a (100 mg, 0.67 mmol) in MeOH (10 mL) were added propionaldehyde (387 mg, 6.66 mmol) and NaBH\(_3\)CN (84 mg, 1.33 mmol) at 0 °C. After stirring for 15 min at 0 °C the mixture was warmed up to rt. After 18 h 2N HCl was added. Subsequently, the mixture was basified by addition of saturated aqueous NaHCO\(_3\). Then, Et\(_3\)O was added and the organic layer was dried (MgSO\(_4\)) and evaporated and the residue was purified by flash chromatography (gradient: petroleum ether - EtOAc 9:1 to petroleum ether - EtOAc 4:1) to give pure 11 (43 mg, 28 %) and pure 12 (43 mg, 28 %), both as colorless oils.
