INDOLIZINES AND AZA-ANALOG DERIVATIVES THEREOF AS CNS ACTIVE COMPOUNDS

The present application relates to indolizine-based compounds of the general formula (I) and aza-analogs thereof, which have medical utility, for example as antipsychotics.
Indolizines and aza-analog derivatives thereof as CNS active compounds

Background:

Schizophrenia and other psychotic disorders including manic phases of bipolar disorder, acute idiopathic psychotic illnesses, and other conditions marked by severe agitation exhibit major disturbances in reasoning, often with delusions and hallucinations. Schizophrenia affects about 1% of the population and about 5-10% of the affected patients commit suicide. The cost to the society is assessed to be several billions of dollars, and there is thus a significant need to provide effective pharmacological treatment options for the treatment of schizophrenia and other psychotic disorders.

It is currently believed that excessive dopamine activity is one of the major underlying causes of schizophrenia. Support for this hypothesis comes from the observation that most of the currently available antipsychotic agents are dopamine D2 receptor antagonists, so called neuroleptics. Examples of typical neuroleptics are haloperidol, loxapine, pimozide, phenothiazine derivatives such as chlorpromazine and fluphenazine, or thioxanthe derivatives such as thiothixene. However, due to their strong and selective D2 antagonism, these first generation antipsychotics have a substantial risk of adverse extrapyramidal neurological side effects as well as an increased release of prolactin. Also, pure D2 antagonists only have an impact on the so-called “positive symptoms” of psychotic disorders, like delusions and hallucinations, which are caused by the overexpression of dopamine receptors in some brain segments but are not effective on “negative symptoms” such as apathy or alogia which are thought to be caused by reduced dopaminergic activity in other areas of the CNS. Finally, about 30% of the patients do not respond well to typical D2 antagonists.

As a consequence, “atypical antipsychotics” or “2nd generation antipsychotics” have been developed. Examples include clozapine, risperidone, and ziprasidone. Atypical antipsychotics have a more complex receptor profile than first generation antipsychotics and besides showing high affinity binding to and inhibition of dopaminergic D2 receptors, also modulate other receptors, like serotonergic and/or adrenergic receptors. For example, clozapine also interacts with a couple of adrenergic, serotonergic, muscarinergic and histaminergic receptors and has proved effective in patients who respond poorly to standard neuroleptics (Goodman&Gilman’s “The pharmacological Basis of therapeutics”, Editor Laurence L. Brunton, 11th edition, 2005). Likewise, risperidone and ziprasidone are
combined D2/5-HT2a receptor antagonists and 5-HT1a agonists. It was thus suggested that atypicality may arise from interactions with the 5-hydroxytryptamine 5-HT2 receptor in addition to the dopaminergic D2 antagonism. Compounds also acting as serotonin 5-HT1A agonists may additionally alleviate negative symptoms of schizophrenia and reduce the likelihood of extrapyramidal symptoms.

A full blockade of D2 receptors can lead to dopamine hypoactivity which is associated with side effects such as extrapyramidal motor dysfunction. A novel strategy to overcome this shortcoming of existing antipsychotics is thus the development of partial dopamine receptor antagonist. Such compounds, like aripiprazole and bifeprunox, are sometimes called “3rd generation antipsychotics”, and do act as antagonist at D2 when there is an overstimulation of dopamine receptors while activating these D2 receptors when there is insufficient stimulation by endogenous dopamine. It is thus believed that partial D2 agonists act as “dopamine stabilisers”, and offer the advantage of full therapeutic efficacy with minimal side effect liability.

Moreover, the modulation of the dopaminergic D3 and the D4 receptors is thought to be useful in the treatment of cognitive and affective symptoms associated with psychotic diseases.

The chemical structures of clozapine, risperidone, ziprasidone and aripiprazole are depicted below:
In one embodiment, the present patent application provides novel compounds that show high affinity to the dopaminergic D2 receptor, but which also interact with significant affinity with the 5-HT2 serotonergic receptor, the 5-HT1a serotonergic receptor and the dopaminergic D3 and D4 receptors.

A preferred embodiment of the present invention relates to new compounds which exert partial dopaminergic activity at the D2 receptor e.g. by having an intrinsic dopaminergic D2 activity that is up to about 50% of a full agonist.

It has been now found, surprisingly, that in one embodiment indolizine derivatives having the general formula A

![Chemical Structure](image)

exhibit the target profile of a modern atypical antipsychotic.

In particular, the compounds as described in more detail further below and in the claims inter alia have a remarkable affinity at the D2 receptor, and do also show binding to the 5-HT2, the 5-HT1a, the D3 and D4 receptors in a range comparable to or even superior than other atypical antipsychotics like aripiprazole.

\text{\quad (R1)ₗm}
\end{array} \quad \text{H} = \text{O} \\
\begin{array}{c}

\text{\quad (R1)ₗm}
\end{array}
\]

\[
\begin{array}{c}
\text{formula XVIa} \\
\text{\quad (R1)ₗm}
\end{array} \quad \text{H} = \text{O} \\

Example E21:
5-[4-[4-(2,3-Dichlorophenyl)piperazin-1-yl]butoxy]pyrazolo[1,5-a]pyridine-3-carbaldehyde

For the synthesis 360 mg (0.86 mmol) 5-[4-[4-(2,3-dichlorophenyl)piperazin-1-yl]butoxy]pyrazolo[1,5-a]pyridine (E15), 2.75 ml dry dimethylformamide and 0.25 ml (2.66 mmol) phosphoroxychloride were stirred at room temperature for one hr. Then, water was added and the mixture was adjusted to basic conditions with 5N NaOH. After extraction with chloroform, the organic layer was dried with Na₂SO₄ and evaporated. The crude product was purified by flash-chromatography (CH₂Cl₂/MeOH 98:2 and subsequently with 95:5).

(b) Biological Activity - In vitro tests: Receptor binding and functional experiments

Biological activity of the Example compounds has been determined in radioligand binding assays. These experiments have been done according to methods which are described in literature (Hübnner, H.; Haubmann, C.; Utz, W.; Gmeiner, P. et al. J. Med. Chem. (2000), 43, 756-762). For the determination of binding affinity to the receptors of the dopamine D2 family membranes were established carrying the human D2long, D2short, D3 or D4.4 receptor subtype expressed in Chinese hamster ovary cell lines. In principle, the binding experiments started when incubating an appropriate amount of membrane with the radioligand [3H]spiperone and the particular test compounds diluted in a wide range of different concentrations from subnanomolar up to micromolar. In the same way binding affinities of the test compounds to the dopamine D1 receptor were determined when using native membrane preparations from porcine striatum and the D1 selective radioligand [3H]SCH 23390.

The investigation of receptor binding to the serotonin and adrenergic receptors was done according to a published procedure (Heindl, C.; hübnner, H.; Gmeiner, P. Tetrahedron: Asymmetry (2003), 14, 3141-3152). In detail, for the serotonin receptors membrane preparations from porcine cortical material was incubated with the 5-HT1A selective radioligands [3H]8-OH-DPAT and [3H]WAY 100635 and the 5-HT2 selective compound [3H]ketanserin. For the determination of alpha receptor binding cortical membranes and the radioligands [3H]prazosin (for α1) and [3H]RX821002 were established in identical manner.

The results of the binding experiments are summarized in Table 1 as mean values of 2 to 4 individual experiments each done in triplicate and expressed as Ki values in nM. Table 1 shows that with two exceptions all presently disclosed compounds have a Ki value at the D2s and D2l receptors of 300 nM or less. 32 of the 61 tested compounds even have a Ki value at the D2 receptors of 10 nm or less.
Table 1: Results of binding assays with dopaminergic and serotonergic receptors

Ki-values given: A ≤ 30nM; B = 30-300 nM; C = 301-3000 nM; D > 3μM

Moreover, most of the compounds of the present invention exhibit a remarkable affinity to at least one of the tested serotonin receptors. While aripiprazole shows a pronounced selectivity for the D2 receptors over the D4.4 receptor as well as over the 5-HT1a (about 40 fold) and the 5-HT2A receptor (about 330 fold), many of the presently disclosed compounds are less selective compared to D4.4 and the serotonin receptors and tend to have a more “balanced” dopamine/serotonin and D2/D4.4 ratio, which may be associated with a reduced likelihood of extrapyramidal symptoms and an increased potency to alleviate negative symptoms of schizophrenia.

The investigation of functional activity was determined when measuring the binding of [35S]GTPγS to membranes after stimulation of the appropriate receptor as published in literature (Schlotter, K.; Boeckler, F.; Hübner, H.; Gmeiner, P. J. Med. Chem. (2005), 48, 3696-3699).

Table 2 shows the functional (intrinsic) activity of the compounds according to the present disclosure at the dopamine D2short receptor as a representative target molecule utilizing the GTPγS-incorporation assay when the intrinsic activity is given based on % activity of quinpirol: A=Full antagonist (<15%); B=weak partial agonist (15-40%) C=strong partial agonist (40-75%) D=Full agonist (>75%).

(c) Biological Activity - In vivo tests: Auditory startle response and prepulse inhibition experiments

Pharmacological tests have been conducted using young adult, male mice which were housed under standard conditions until testing when they were in the age of 8 to 9 weeks. Auditory startle response and prepulse (weak auditory stimulus) inhibition were used as a tool for assessment of deficiencies in sensor-motor gating, such as those seen in schizophrenia.

Mice were placed in a PPI chamber for acclimation and then treated with different trials including null (no stimuli), startle (120 dB), startle plus prepulse (4, 8 and 12 dB over background noise) or prepulse alone (82 dB). Data was analyzed by repeated measures analysis of variance (ANOVA) followed by post-hoc analysis when appropriate. An effect was considered significant if p < 0.05.

The following test compounds have been investigated as representative examples: E16, E21, E22, E36 and E37 whose stimulating effects were compared to that induced by the reference compound aripiprazole.

Table 3 shows the results of the auditory startle response and the effects on prepulse inhibition induced by the test compounds at doses of 1, 3 and 10 mg/kg when E16, E22
and E37 show a dose-dependent PPI and when E16 enhances PPI at doses with no startle effect similar to the effects of aripiprazole.

Table 3: In vivo effect of representative examples of the presently disclosed compounds on the auditory startle response (ASR) and prepulse inhibition (PPI) in mice at doses of 1, 3 and 10 mg/kg

(d) Biological Activity - Comparative study with indolizine based example compounds bearing an ether bridged linker or a carboxamide linker

The indolizine based example compounds of the present patent application show a remarkable affinity at the D2 receptor, and also show binding to the 5-HT2, the 5-HT1a, the D3 and D4 receptors in a range comparable to or even superior than other atypical antipsychotics like aripiprazole.

These results are unexpected because structurally related indolizine derivatives are published as highly dopamine D3 receptor affine compounds with a remarkable selectivity over D2 receptors (see Table 4) (WO 2006/015737; Bettinetti, L., Schlotter, K., Huebner, H., Gmeiner, P. J. Med. Chem. (2002), 45, 4594-4597). These D3 selective compounds are always bearing a carboxamide moiety, especially a carboxamide butyl linker.

Surprisingly, we found out in this application that combining the indolizine subunit and the phenylpiperazine substructure by an ether alkylene group, especially an oxybutylene linker, leads to example compounds with high D2 binding affinity and finally to the appropriate balance of binding to the dopamine D2, D3, D4 and the serotonin 5-HT1A receptor subtypes, which is desired for antipsychotic compounds.
Table 4: Comparison of binding profiles of selected indolizines bearing an ether alkylene linker and published derivatives with a carboxamide alkylene spacer. Ki values for the dopaminergic receptors D2long, D2short, D3 and D4 and the serotonergic receptors 5-HT1A and 5-HT2 are given in [nM].
